

What the AI SDR Dashboard adds to QuickMail

QuickMail sends the mail. This app decides what gets sent, catches what comes back, and puts a person in front of anything irreversible.

50,546	359	375	17	401k	10.5%
leads mirrored	campaigns tracked	reply threads	sending mailboxes	emails sent to date	bounce rate — the problem

1 What QuickMail already does and how much of it the API will let us touch

QUICKMAIL FEATURE	IN THE PUBLIC API?	WE USE IT	WHAT WE DO WITH IT
Campaigns & sequences	yes — 24 mutations	yes	Build the whole campaign from the app: steps, waits, senders, sending window, enrolment.
Prospects / leads	yes	yes	50,546 mirrored locally so search and suppression work without hitting the rate limit.
Mailboxes & inbox rotation	yes	yes	17 accounts with the <code>authorized</code> flag — a de-authorised sender is otherwise invisible.
Delivery analytics	yes	yes	Sent, delivered, opens, clicks, replies, bounces per campaign.
Reply inbox ("Opportunities")	counts only	session	The API returns reply <i>totals</i> and no message body. Read through the signed-in browser instead.
Sending / replying	absent	session	No send mutation exists on any public API.
Trigger & go-live	absent	UI clicks	No trigger field at all; <code>paused</code> is writable on steps but never on a campaign.
Do-not-contact	absent	session	Set through their internal operation, together with cancelling the running sequence.
Warm-up & deliverability tooling	absent	—	Stays entirely inside QuickMail. We only read the damage it is meant to prevent.

API public v2 GraphQL, API key

session their internal API, called inside the signed-in browser

UI clicks Playwright driving the real interface

absent not available on any public API

2 The four things QuickMail's API cannot do and how each was solved

NEEDED	WHY THE API CAN'T	ROUTE TAKEN	HOW IT WORKS, AND WHAT IT COST
Read reply content	13 queries, none carry a message body	session	Their own operation, read out of QuickMail's JavaScript bundle and replayed inside the signed-in page. 374 threads, 1,127 messages.
Send a reply	no send mutation exists	session	<code>replyToEmail</code> — threaded onto the original message, from the mailbox that received it. Verified end to end with a real send.
Set trigger, go live	no trigger field; no campaign-level pause	UI clicks	Playwright fills leads/day, days and time, then flips Paused → Live and handles the warnings dialog. Verified through the API afterwards.
Stop a person's sequence	not exposed	session	<code>setProspectsAsDoNotContact</code> plus <code>cancelProspects</code> — one blocks future enrolment, the other kills what is already queued.

Why not just script the whole UI? Clicking is slow and breaks on every redesign. The browser is used for the **session**, and real API calls are issued inside it. Clicking is reserved for the two controls that have no operation behind them at all — the trigger and the live toggle.

Built on top — things QuickMail has no concept of

Everything below exists only in this app. None of it is a QuickMail feature we are re-exposing.

3 Additions the reason the app exists rather than using QuickMail directly

ADDITION	QUICKMAIL EQUIVALENT	WHAT IT GIVES US
Human approval gate	none — actions are immediate	Sending a reply and barring an address each stop at a panel restating exactly what will happen. Both write an audit record of who approved what.
Suppression list	per-prospect do-not-contact	Keyed on the <i>address</i> , not the prospect row, so re-importing a spreadsheet cannot resurrect someone who asked to stop. Blocks enrolment before it ever reaches QuickMail.
Reply classification	returns <code>null</code> on nearly every thread	Six-way sentiment on every reply, so 375 threads narrow to the 138 worth a person's time. Accuracy is measured, not asserted — 46 labelled real replies, 65% → 100%.
AI reply drafting	none	A draft per thread, signed as the mailbox owner, with the quoted history stripped so the model answers the newest message rather than one from three weeks ago.
Campaign agent	none	Turns a written brief into a full campaign spec — audience, sequence, copy, sending window — then builds it through the API.
Campaign scheduling	no start or end date exists	A scheduler pauses and unpauses each email variation to enforce a window QuickMail has no field for.
Pre-send guards	none	Dead-mailbox check, merge-tag validation, suppression gate, and a trailing wait step — each one added after a campaign silently sent nothing.
Full-text reply search	subject and sender only	Searches the message body too — "the one who asked about pricing" is a likelier search than a name.

4 What each capability actually runs on

CAPABILITY	MECHANISM	DEPENDS ON	IF THE DEPENDENCY GOES
Build & enrol a campaign	API	API key	Unaffected by browser or AI outages. This is the stable path.
Trigger & go live	UI clicks	Edge on the debug port, signed in	Falls back to written manual steps; the campaign is still built.
Read, send, stop replies	session	Same browser + QuickMail's internal API	Reports the reason and stops. Nothing sends silently.
Classify & draft	this app	An AI provider — none reachable today	Classification falls to measured rules; drafting to a template. Both say so on screen.
Approvals, suppression, audit	this app	local database only	No external dependency at all.

5 Proven

- Campaign built and launched through the app, end to end
- Real reply sent and confirmed in the live thread
- Stop verified — do-not-contact read back from QuickMail
- All 374 reply threads mirrored, 1,127 messages
- Classifier at 100% on 46 labelled real replies

6 Needs a decision

- 38 people asked to stop** — 16 explicitly — all awaiting a click
- No AI provider funded** — quota exhausted, no Claude key
- 10.5% bounce rate**; worst campaign 80.8% against a 5% ceiling
- Suppression list holds 9 entries against 42,339 bounces
- 5 of 17 mailboxes fail sender assignment — support ticket drafted

The standing risk, stated plainly. Reading replies, sending them and stopping a prospect all depend on QuickMail's own internal API, which is undocumented and can change without notice. Campaign creation does not — that uses the published API and is unaffected. Everything built on the internal route fails loudly rather than quietly.
